**Received 16/1/2003** Accepted 18/1/2003

ABSTRACT: Six populations (P1, P2, F1, F2, B1 and B2) of five wheat crosses, namely 1) Sakha 69 x Sahel 1, 2) Sakha 69 x Shi# 4414/Gow "s" // Seri 82, 3) Sahel 1 x Bocro-4, 4) Gemmeiza 5 x Giza 168 and 5) Shi# 4414/Gow "s" // Seri 82 x Bocro - 4, were raised in a randomized complete block design during the three successive seasons of 1998/1999, 1999/2000 and 2000/2001 at Ismailia Agricultural Research Station, Ismailia Governorate, Egypt. Aim of the study was to determine the adequacy of genetic model and gene action controlling relative water content, transpiration rate, osmotic pressure, proline content, leaf chlorophyll content, flag leaf area, days to heading and grain yield / plant. The results indicated the importance of additive genetic variance (D) in the genetic control of days to heading in all crosses, relative water content in 1<sup>st</sup> cross; transpiration rate in 1<sup>st</sup> and 3<sup>rd</sup> crosses; proline content in 1<sup>st</sup>, 2<sup>nd</sup> and 4<sup>th</sup> crosses; leaf chlorophyll content in 1<sup>st</sup>, 4<sup>th</sup> and 5<sup>th</sup> crosses; flag leaf area 2<sup>nd</sup>, 3<sup>rd</sup>, 4<sup>th</sup> and 5<sup>th</sup> crosses as well as osmotic pressure and grain yield / plant in 3<sup>rd</sup> and 5<sup>th</sup> ones, whereas, the dominance genetic variance (H) was found to be the prevailent type controlling the remaining crosses. Narrow sense heritability was high (>50%) for relative water content, transpiration rate, osmotic pressure, proline content, leaf chlorophyll content, flag leaf area and days to heading in most cases, and ranged from low (25.25%) to moderate (46.95%) for grain yield / plant.

Scaling test, provide evidence of non-allelic interaction in controlling relative water content in 1<sup>st</sup> and 5<sup>th</sup> crosses; transpiration rate in 1<sup>st</sup>, 2<sup>nd</sup> and 4<sup>th</sup> crosses; osmotic pressure and leaf chlorophyll content in 1<sup>st</sup>, 3<sup>rd</sup> and 4<sup>th</sup> crosses; proline content in 1<sup>st</sup>, 2<sup>nd</sup>, 3<sup>rd</sup> and 5<sup>th</sup> crosses; flag leaf area in 2<sup>nd</sup> cross as well as days to heading and grain yield / plant in all crosses. However, the simple genetic model was adequate for explaining the inheritance of relative water content in 2<sup>nd</sup>, 3<sup>rd</sup> and 4<sup>th</sup> crosses; transpiration rate in 3<sup>rd</sup> and 5<sup>th</sup> crosses; osmotic pressure and leaf chlorophyll content in 2<sup>nd</sup> and 5<sup>th</sup> crosses; proline content in 4<sup>th</sup> cross and flag leaf area in 1<sup>st</sup>, 3<sup>rd</sup>, 4<sup>th</sup> and 5<sup>th</sup> crosses. The additive gene effect (d) was more important in the genetic system controlling relative water content and osmotic pressure in 2<sup>nd</sup> cross; transpiration rate in 3<sup>rd</sup> cross; proline content in 4<sup>th</sup> cross; leaf chlorophyll content in 5<sup>th</sup> cross and flag leaf area in all crosses except 2<sup>nd</sup> one. The additive (d) and its digenic interaction type additive x additive (i) were significant and involved in the inheritance of days to heading in 1<sup>st</sup> cross. However, the dominance (h) and dominance x dominance (l) were involved in the genetic control of osmotic pressure in 1<sup>st</sup>, 3<sup>rd</sup> and 4<sup>th</sup> crosses; proline content in 1<sup>st</sup> cross; days to heading in 1<sup>st</sup> and 3<sup>rd</sup> crosses as well as grain vield / plant in 3rd one. The additive x dominance (j) was significant for relative water content in 1<sup>st</sup> cross; osmotic pressure in 3<sup>rd</sup> cross: proline content in 3<sup>rd</sup> and 5<sup>th</sup> crosses; Leaf chlorophyll content in 1<sup>st</sup> and 3<sup>rd</sup> crosses; days to heading in 2<sup>nd</sup> cross and grain yield/plant in 2<sup>nd</sup> and 4<sup>th</sup> crosses.

# INTRODUCTION

Improving drought tolerance of wheat has long been a major challenge of most breeding programs because water deficit during critical stages of wheat life are common to most regions of the world where wheat is produced. At the present, the best and ultimate indicator of drought resistance used in wheat breeding programs is grain yield measured under well - watered and water – stress conditions. The effects of drought on the physiology of plants and crops are well documented and putative physiological traits associated with drought resistance have been identified (Ludlow and Muchow 1990; Turner 1997). Plant breeders have measured selected physiological parameters like relative water content, transpiration rate, osmotic pressure, proline content, leaf chlorophyll content, flag leaf area and days to heading supplimented grain yield / plant for the purpose of identifying selection criteria which would be used to screen germplasm for drought tolerance.

Therefore. studying the type of gene action controlling physiological characters along with wheat grain yield accounted the major importance in wheat breeding program. Since, decision making about the effective breeding procedure to be used is mainly dictated by the type of gene action controlling the physiological characters. Thus, the genetic information obtained from multigeneration are reliable compared with those based on one generation, thus six populations  $(P_1, P_2, F_1, F_2, B_1 \text{ and } B_2)$  are considered the one which may give detailed information for the employed genotypes.

Assessment the type of gene action in wheat have been studied by many investigators, and they reported that epistasis and non-additive gene effects, contributed an important role in

the inheritance of days to heading and grain vield (Ketata et al., 1976) and days to heading only (Eissa 1994; Hassan 1993 and Awaad 1996 and 2002). Additive and dominance gene action and their digenic interaction. (additive x additive), (additive x dominance) and (dominance x dominance) more important in the were inheritance of grain vield / plant (Singh et al., 1985; Awaad, 1996 and 2002 and Salama 2002). Dedio concluded from (1975) а controlled-environment study of a wheat cross. Pitic 62 x ACEF-125. that the water retention trait was under simple genetic control and governed by genes with dominant effect. Whereas Dhanda and Sethi (1998) concluded that additive gene action played a major role in determining the inheritance of relative water content. and selection for this trait appeared to more effective at anthesis. be Heritability of initial minus wilted water concentration ranged from 0.08 to 0.61 in the  $F_4 / F_6$  and from 0.15 to 0.41 in  $F_6/F_8$  comparisons Townley-Smith, (Clarke and 1985). The transpiration efficiency inherited was simply and controlled mainly by additive genetic variation which was reflected in high (88 to 89%)

narrow sense heritability (Malik et al., 1999).

The predominant of nonadditive gene action controlling leaf chlorophyll content, flag leaf area and grain yield/plant was reflected in moderately low narrow sense heritability (Ismail et al., 2000 and Awaad, 2001) as well as grain yield / plant and proline content (Hassan, 2002). However, additive genetic variance was found to be the prevailed type controlling the inheritance of days to heading and flag leaf area reflecting high heritability estimates in narrow sense (Salem et al., 2000 and Awaad, 2002) as well as days to heading with moderate heritability in narrow sense (Salama, 2002).

This investigation was performed to study the inheritance of some physiological characters related to drought tolerance using generation mean analysis.

## MATERIALS AND METHODS

The present investigation was conducted during the three winter growing seasons; 1998/ 1999, 1999/2000 and 2000/2001 at Ismailia, Agricultural Research Station, Ismailia Governorate. Five wheat crosses have been used in the present study derived from six diverse parental bread wheat genotypes (Table 1). These genotypes were used to obtain the following five crosses; 1) Sakha 69 x Sahel 1, 2) Sakha 69 x Shi # 4414/Gow "s"// Seri 82, 3) Sahel 1 x Bocro - 4, 4) Gemmeiza 5 x Giza 168 and 5) Shi # 4414/Gow "s"// Seri 82 x Bocro-4.

In the first season of 1998/1999, the six parental wheat genotypes were evaluated in a randomized complete block design with three replications, at the meantime. pair crosses were performed to obtain  $F_1$ 's grains. In the second season, 1999/2000, five  $F_1$  cross grains were sown to produce  $F_1$  plants. Each of the  $F_1$ plants were crossed back to their respective parents to produce first  $(F_1 \times P_1)$  and second  $(F_1 \times P_2)$ backcrosses. In the meantime, pair crosses were made to produce more  $F_1$  grains, also the  $F_1$  plants were selfed to produce  $F_2$  grains. In the third season, 2000/2001, the obtained grains of six populations  $(P_1, P_2, F_1, F_2, B_1 \text{ and } B_2)$  for each of the five crosses were evaluated using a randomized complete block design with three replications. Wheat grains were the last week of sown on November. Row was 2m long, row to row and plant to plant spacings were 20 and 5cm, respectively.

**Table (1):** Pedigree of the evaluated bread wheat genotypes.

The normal agricultural practices for wheat production under sandy soil conditions were performed. Data of days to heading and flag leaf area were recorded at the time of full emergence of main spike, meanwhile at grain filling relative water content period, (Barrs, 1968), transpiration rate (Stocker, 1956 and Gosav 1960), leaf osmotic pressure (Gosav, 1960), proline content (Bates et al., 1973) were performed in penultimate leaf, also flag leaf chlorophyll content was estimated apparatus using **SPAD-502** (Castelli et al., 1996). Moreover, at harvest grain yield per plant (gm) has been estimated.

#### **Biometrical assessment:**

A regular analysis of variance was firstly performed for the studied characters of the five wheat crosses.

#### Testing the genetic model:

The A, B, C and D scaling tests as outlined by Mather and Jinks (1982) were applied to test

of non-allelic the presence interactions as follows; A=2B<sub>1</sub>-P<sub>1</sub>- $F_1$ ,  $B=2B_2-P_2-F_1$ ,  $C=4F_2-2F_1-P_1-P_2$ and  $D=2F_2-B_1-B_2$ . Due to unknown biased effect of nonallelic interaction, the simple genetic model (m, d and h) was applied when epistasis was absent. Whereas, in the presence of nonallelic interaction, the analysis was proceeded compute to the . interaction types involved using the six-parameters genetic model according to Jinks and Jones (1958). The significancy of the genetic components were tested using the "t" test where:

$$t = \frac{Effect}{Variance of effect}$$

# Components of the genetic variance:

The components of genetic variance for each character in the studied crosses were partitioned into additive (D), dominance (H) genetic variances and environmental (E) one using Mather and Jinks (1982) formulae as follows:

$$E = (1/3) (VP_1 + VP_2 + VF_1)$$
  
D = 4 VF\_2 - 2 (VB\_1 + VB\_2) and  
H = 4 (VF\_2 - <sup>1</sup>/<sub>2</sub> VD - E)

The genetic components of variance were used further to compute average degree of dominance  $(H/D)^{1/2}$  and heritability in broad sense (Tb) wheare:

$$Tb = \frac{1/2D + 1/4H}{1/2D + 1/4H + E}$$

and in narrow sense (Tn) whereas;

$$Tn = \frac{1/2D}{1/2D + 1/4H + E}$$

#### **RESULTS AND DISCUSSION**

## I- Mean performance:

The reliability of the genetic components estimates depends mainly on the amount of the genetic variability among the studied genotypes. Before proceeding to the biometrical analyses the "t" statistical test was applied to the studied genotypes for the different characters. The results revealed significant

differences between parental genotypes, providing evidence for the presence of considerable amount of genetic differences among genotypes. Data of mean performance (Table 2 and 3) indicated that the  $F_1$ 's exceeding the high performing parent for relative water content in 3rd and 5th crosses; transpiration rate in 2<sup>nd</sup> and 5<sup>th</sup> crosses; osmotic pressure in 5<sup>th</sup> cross; leaf chrophyll content in 2<sup>nd</sup> and 4<sup>th</sup> crosses; flag leaf area in 2<sup>nd</sup>, 4<sup>th</sup> and 5<sup>th</sup> crosses, days to heading in 2<sup>nd</sup> and 4<sup>th</sup> crosses and grain yield / plant in all crosses except 4<sup>th</sup> cross, showing the importance of over-dominance and positive heterotic effect which may result in adequate genetic base for further improvement. While the  $F_1$ 's means were less than the lower parent for relative water content in 4<sup>th</sup> cross; transpiration rate in 1<sup>st</sup> and 4<sup>th</sup> crosses; osmotic pressure in 1<sup>st</sup> cross; proline content in 1<sup>st</sup> and 2<sup>nd</sup> crosses; leaf chlorophyll content in 5<sup>th</sup> cross; flag leaf area in 1<sup>st</sup> cross as well as days to heading in 1<sup>st</sup> and 3<sup>rd</sup> ones; providing evidence for the predominant of decreasing and negative heterotic alleles effect. The  $F_1$ 's means were equal to the lower parent for osmotic pressure in 4<sup>th</sup> cross and proline content in 1<sup>st</sup> cross,

Table (3): Mean  $\pm$  S.E. for the six populations for leaf chlorophyll conten, flag leaf area, heading date and grain yield / plant in five wheat crosses.

~

58

showing complete dominance mode of inheritance.

II- Components of the genetic variance and heritability:

Separate out the total genetic variance to its constituent parts: additive (D) and dominance (H) gene effects has been done. Also, heritability in broad (Tb) and narrow (Tn) senses were calculated. The results given in Tables (4 and 5) clearly indicate that additive genetic variance (D) predominant was the type controlling days to heading in all studied wheat crosses; relative 1<sup>st</sup> cross: content in water transpiration rate in 1<sup>st</sup> and 3<sup>rd</sup> crosses; osmotic pressure in 3rd and 5<sup>th</sup> crosses; proline content in  $1^{\text{st}}$ ,  $2^{\text{nd}}$  and  $4^{\text{th}}$  crosses; leaf chlorophyll content in 1<sup>st</sup>. 4<sup>th</sup> and 5<sup>th</sup> crosses; flag leaf area in all crosses except the 1<sup>st</sup> one and grain yield/plant in 3<sup>rd</sup> and 5<sup>th</sup> crosses, resulting in (H/D)<sup>0.5</sup> ratio was less unity. reinforcing the than importance role of phenotypic selection for improving these characters in the corresponding crosses. Similar conclusion was reported for days to heading, flag leaf area and grain yield (Eissa and Awaad, 1993 and Salem et al., 2000) and for days to heading, flag

leaf area, and leaf chlorophyll content (Awaad, 2002).

dominance genetic The variance was found to be the prevailed type in the inheritance of relative water content in 1<sup>st</sup>, 2<sup>nd</sup>, 3<sup>rd</sup> and 5<sup>th</sup> crosses: transpiration rate in  $2^{nd}$ ,  $4^{th}$  and  $5^{th}$  crosses; osmotic pressure in 1<sup>st</sup>, 2<sup>nd</sup> and 4<sup>th</sup> crosses: proline content in 3rd and 5th crosses: leaf chlorophyll content in 2<sup>nd</sup> and 3<sup>rd</sup> crosses; flag leaf area in 1<sup>st</sup> cross and grain yield / plant in 1<sup>st</sup>, 2<sup>nd</sup> and 4<sup>th</sup> ones, resulting in  $(H/D)^{0.5}$  ratio was more than unity. indicating the importance of overdominance gene effects in the genetic control of these characters in those crosses. In this respect, hybrid breeding method could be used for improving these characters and also, in this connection. dominance gene effect played an important role in the inheritance of leaf chlorophyll content (Ismail et al., 2000), grain vield/plant (Hassan, 1998 and 2001) as well as Awaad. proline content in leaves (Hassan, 2002).

Heritability estimates in narrow sense (Tn) was high (>50%) for relative water content in  $1^{st}$  and  $4^{th}$  crosses; transpiration rate and osmotic pressure in  $1^{st}$ ,  $3^{rd}$ and  $5^{th}$  crosses; proline content in

Table (5): Components of variance (D, H and E) and heritabilities (T<sub>b</sub> and T<sub>n</sub>) for Chlorophyll content (SPAD value), flag leaf area cm<sup>2</sup>, days to heading and grain yield / plant (g) in five wheat crosses.

and 4<sup>th</sup> crosses; leaf  $1^{\text{st}}$ ,  $2^{\text{nd}}$ chlorophyll content in 1<sup>st</sup>, 2<sup>nd</sup>, 4<sup>th</sup> and 5<sup>th</sup> crosses; flag leaf area in all crosses except the 1<sup>st</sup> cross, days to heading in  $1^{st}$ ,  $3^{rd}$  and  $4^{th}$  crosses. These results allowing for considerable progress from selection. In this respect, high "Tn" values have reported for days to heading and flag leaf area (Salem et al.. 2000); leaf chlorophyll content (Awaad, 2002) and transpiration effeciency (Malik et al., 1999). Selection for greater transpiration efficiency offers potential for improving biomass and grain yield when these are limited by available water (Rebetzke et al., 2002).

Heritability in narrow sense was low for grain yield / plant and ranged from 25.25 to 46.95%, where vield is quantitively inherited and greatly affected by environmental changes, as well as low to moderate "Tn" estimates were reported in the remaining crosses for the various characters. Similar results were recorded for days to heading (Mossad, 1991; Awaad, 2002 and Salama, 2002); leaf chlorophyll content and grain vield/plant (Ismail et al., 2000 and Awaad, 2001 and 2002) and for grain yield / plant (Eissa and Awaad, 1993; Awaad, 1996 and Hassan, 2002).

# III- Adequacy genetic model and gene effects:

The presence of epistasis result in biased estimates of the genetic components of variance (Mather and Jinks 1982), therefore in the present study (A, B, C and D) scaling to test for epistasis was employed. The results (Tables 6 and 7) indicated significant nonallelic interactions for days to heading and grain yield/plant in all crosses; relative water content in 1<sup>st</sup> and 5<sup>th</sup> crosses; transpiration rate in 1<sup>st</sup>, 2<sup>nd</sup> and 4<sup>th</sup> crosses; osmotic pressure and leaf chlorophyll content in 1<sup>st</sup>, 3<sup>rd</sup> and 4<sup>th</sup> crosses; proline content in 1<sup>st</sup>, 2<sup>nd</sup>, 3<sup>rd</sup> and 5<sup>th</sup> crosses as well as flag leaf area in 2<sup>nd</sup> one. These results indicate the presence of epistasis, and the digenic model was adequate to explain the genetics of the abovementioned characters in the corresponding crosses. Similar findings were for grain yield/plant reported Amawate and Behl (1995) and for grain yield / plant and leaf chlorophyll content by Awaad (2002).

The insignificancy of non allelic interaction tests for relative water content in  $2^{nd}$ ,  $3^{rd}$  and  $4^{th}$  crosses; transpiration rate in  $3^{rd}$  and  $5^{th}$  crosses; osmotic pressure

<b>Table (7):</b> Non-allelic interaction tests	(A, B, C and D) along with six parameter model for	chlorophyll content, flahe leaf area,
days to heading and grain y	ield/plant in five wheat crosses.	

64

and leaf chlorophyll content in  $2^{nd}$ and  $5^{th}$  crosses; proline content in  $4^{th}$  cross and flag leaf area in  $1^{st}$ ,  $3^{rd}$ ,  $4^{th}$  and  $5^{th}$  crosses, indicating that the simple additive-dominance genetic model proved to be satisfactory in explaining the inheritance of the foregoing characters. Similar results were reported for days to heading (Awaad, 1996 and 2002 and Salama, 2002).

The adequacy of genetic model (Tables 6 and 7) indicated that the additive gene effect (d) was the main type controlling the inheritance of relative water content and osmotic pressure in 2<sup>nd</sup> cross: transpiration rate in 3<sup>rd</sup> cross: proline content in 4<sup>th</sup> cross; leaf chlorophyll content in 5<sup>th</sup> cross and flag leaf area in 1<sup>st</sup>, 3<sup>rd</sup>, 4<sup>th</sup> and 5<sup>th</sup> crosses. Meanwhile, the additive (d) and additive x additive (i) interaction type were important in the genetic system controlling days to heading in 1<sup>st</sup> one; indicating that the superior could genotypes efficiently identified from its phenotypic expression. Therefore phenotypic selection was more effective for improving these characters. Similar results were reported by many investigators (Mosaad, 1991; Awaad, 1996; Dhanda and Sethi, 1998; Islam et al., (1998);

Malik et al., 1999 and Awaad, 2002).

The dominance (h) and its digenic interaction type. dominance x dominance (i) were significant and involved in the inheritance of osmotic pressure in 1<sup>st</sup>, 3<sup>rd</sup> and 4<sup>th</sup> crosses; proline content in 1<sup>st</sup> cross; days to heading in 1<sup>st</sup> and 3<sup>rd</sup> crosses as well as grain yield / plant in 3<sup>rd</sup> one. The considerable amount of non-fixable gene action type displayed by these characters in the corresponding crosses may suggest that improving these could be achieved characters through hybrid breeding method. Similar results were detected by Awaad (2002) and Hassan (2002).

Meanwhile, the interaction type additive x dominance (i) was negative and significant for relative water content in 1<sup>st</sup> cross; osmotic pressure in 3<sup>rd</sup> cross; proline content in 3rd and 5th crosses; leaf chlorophyll content in 1<sup>st</sup> and 3<sup>rd</sup> crosses: days to heading in 2<sup>nd</sup> cross and grain yield / plant in 1<sup>st</sup> and 4<sup>th</sup> crosses. Suggesting that decreasing alleles were more frequent than the increasing ones, and vice versa was recorded for leaf chlorophyll content in 3<sup>rd</sup> cross and days to heading in 1<sup>st</sup>,

 $3^{rd}$ ,  $4^{th}$  and  $5^{th}$  crosses, which showing more frequent of increasing alleles over decreasing ones. Also, the interaction types of (j) and (i) were highly significant for grain yield / plant in  $1^{st}$  and  $4^{th}$ crosses.

#### Salem, et . al.

الورقة، ومساحة ورقة العلم، عدد الأيام حتى طرد السنابل في معظــم الـــهجن، ومنخفضـــة (٢٥,٢٥%) إلى متوسطة (٤٦,٩٥%) لمحصول حبوب النبات.

أظهرت نتائج إختبار المقياس (A, B, C and D) أن الموديل الوراثي المعقد هو الملائم لتفسير وراثة صفات؛ محتوى الورقة النسبي من الماء في الهجينين الأول والخــامس، معدل النتح في الهجين الأول والثاني والرابع، الضغط الأسموزي ومحتوى كلوروفيل الورقسة. في الهجين الأول والثالث والرابع، محتوى البرولين فــي الــهجين الأول والثــاني والثــالث والخامس، مساحة ورقة العلم في الهجين الثاني، وكذلك عند الأيام حتــــي طــرد الســنابل ومحصول الحبوب/نبات في جميع الهجن. في حين كان الموديل الور اثي البسيط هو الملائهم لتفسير وراثة صفات؛ محتوى الورقة النسبي من الماء في الهجين الثاني والثــالث والرابـــع، معدل النتح في الهجينين الثالث والخامس، الضغط الأسموزي ومحتوى كلورفيل الورقة فـــي الهجينين الثاني والخامس، محتوى البرولين في الهجين الرابع فقط، ومساحة ورقة العلم فـــي الهجين الأول والثالث والرابع والخامس. وكان الفعل الجيني المضيف هو الأكثر أهمية فــــي وراثة صفات؛ محتوى الورقة النسبي من الماء والضغط الأسموزي في الهجين الثاني، معدل النتح في الهجين الثالث، محتوى البرولين في الهجين الرابع، محتوى كلوروفيل الورقة فـــي الهجين الخامس، ومساحة ورقة العلم في جميع الهجن ماعدا الهجين الثاني. كما كان الفعـــل الجيني المضيف والتفاعل (مضيف × مضيف) ذو أهمية في وراثة صفة عدد الأيام حتبي طرد السنابل في الهجين الأول. بينما كان الفعل الجيني السيادي والتفاعل (سيادي × سـيادي) هو المتحكم في وراثة صفات؛ الضغط الأسموزي في الهجين الأول والثالث والرابع، محتوى ا البرولين في الهجين الأول، عدد الأيام حتى طرد السنابل فـ السهجينين الأول والثسالث، ومحصول الحبوب/نبات في الهجين الثالث فقط. وقد كان التفاعل (مضيف × سيادي) معنويــا في صفات؛ محتوى الورقة النسبي من الماء في الهجين الأول، الضغط الأسموزي في الهجين الثالث، محتوى البرولين في الهجينين الثالث والخامس، محتوى كلوروفيل الورقية في الهجينين الأول والثالث، عدد الأيام حتى طرد السنابل في الهجين الثاني ومحصول الحبسوب/ نبات في الهجينين الأول والرابع.
