SUMMARY

The objectives of the present study were to evaluate the effects of recombinant bovine somatotropin (rbST) on milk production, and composition and some hematobiochemical characteristics in Damascus goats. Fifteen Damascus lactating goats in their third to fourth lactation season and at 30-40 days postpartum were divided into three equal groups. The first group was served as control, while the second and the third groups were subcutaneously and biweekly injected for 8 weeks, with low (50 mg/does) or high (100 mg/does) doses of rbST, respectively. Administration with rbST resulted in a significant ($P < 0.05$) increase in total milk yield by 24.3 and 22.5 % for 50 mg or 100 mg of rbST, respectively compared with control. Body weight and dry matter intake of does were not affected significantly by rbST treatment. While, average daily gain (ADG) of kids suckling rbST-treated does was higher by (11 and 10.5 % for low and high doses of rbST, respectively) than for kids of control does during the treatment period. Administration with rbST caused insignificant ($P > 0.05$) increase in the levels of total solids, milk protein and fat compared with control, while lactose was significantly ($P < 0.05$) increased. On the other hand, ash, hematological parameters, plasma proteins and the activities of plasma aspartate aminotransferase (AST), alanine aminotransferase (ALT), glutathione S-transferase (GST), alkaline phosphatase (ALP), acid phosphatase (AcP), and the levels of thiobarbituric acid-reactive substances (TBARS), creatinine and cholesterol were not significantly affected by the treatments. Administration of rbST significantly ($P < 0.05$) increased the concentrations of plasma glucose and decreased those of urea and total bilirubin. The results of the present study suggest that rbST is efficacious in increasing milk yield and kid growth up to 50 mg/14 d without adverse effects on lactating goats.

Keywords: Somatotropin; Goat; Milk composition; Blood metabolites.

INTRODUCTION

Previous studies have demonstrated that somatotropin is a key control of nutrient use. When bovine somatotropin (bST) is exogenously administered, markedly

improves productive efficiency in lactating cows (Peel and Bauman, 1987; Bauman, 1992). Lactational responses to bST have been reported for all dairy breeds examined, including North American and European breeds as well as Murrah buffalo. In addition, animals of different parities and genetic potentials are responsive to bST (Peel and Bauman, 1987). Improvement of productive efficiency and economic profit is an important goal in dairy farming, as in any agricultural enterprise. With bST use, a unit of milk is produced with less feed and protein supplement and with a reduction in animal excreta (manure, urine, and methane). Nationally, the use of bST simply reinforces, but does not fundamentally change dairy industry trends of increased milk yield per cow, reduced number of cows, and declines cow and dairy farm numbers (Bauman, 1992). Administration of exogenous native pituitary or recombinant bovine somatotropin (rbST) significantly increases milk yield in dairy cattle, either in short- (Chilliard, 1988a) or long-term (Chilliard, 1988b) experiments. Bauman (1992) reported that the maximum milk response is achieved at a bST dose (daily injection) of about 30 to 40 mg/d, and no further increase occurs even at doses several fold higher. Although, the treatment of lactating sheep and goats with rbST resulted in an increased milk yield, but the trials with sheep and goats were of very short-term (<14d.) which allowing a weak galactopoietic effect (Disenhaus *et al.*, 1995). From the previous studies, there is a few experiments have been carried out with bST on lactating goats to investigate its repeated daily doses for short-term (<14 d.), but not for long-term and weekly or biweekly injection. Therefore, this study was carried out to investigate the effects of two different doses of rbST, administrated biweekly in lactating goats on milk yield, milk composition, kids growth performance and some blood metabolites of lactating goats with single kid for 8 weeks.

MATERIALS AND METHODS

Animal management and treatments

The experiment was carried out at the Alexandria University Experimental Farm during spring 2003. Fifteen lactating Damascus does each weighing 29.12 ± 1.34 kg with single kids at 30-40 days postpartum were used. Goats were in their third to fourth lactation season. The goats were kept in a free stall and had free access to water. They were fed on concentrate mixture and berseem hay twice daily at 0700 and 1500 h. The diet was offered in amounts calculated to provide 120% of the NRC recommended amount (NRC, 1985). Individual intakes of berseem hay and concentrate were recorded daily. Weight of refusal feeds were recorded once daily. Feed was sampled once weekly and monthly was composite dried and ground. Berseem hay and concentrate were analyzed for dry matter (DM), crude protein (CP), ether extract and ash according to procedures of AOAC (1990) (Table 1). The animals were divided into 3 homogenous groups, 5 animals each, according to lactation stage, parity and milk yield. The first group was used as a control, while the second and third groups were subcutaneously injected with 50 or 100 mg rbst/doe biweekly for 60 days. A sustained release formulation of rbST was purchased from Elanco-Eli Lilly export S.A., Geneva.

Table 1. Chemical composition of commercial concentrate mixture and berseem hay

Parameters (%)	Concentrate	Berseem hay
Dry matter	89.44	91.45
Organic matter	83.59	80.33
Crude protein	12.45	11.05
Crude fiber	4.92	22.35
Ether extract	4.75	2.65
Ash	5.85	11.12
Nitrogen free extract (NFE)	61.47	44.28

Milk production and composition

Milk yield was recorded twice weekly at 0700 and 1600 h by using weigh-suckle-weigh technique (Williams *et al.*, 1979). At approximately 0800am, kids were removed from their dams and placed in an adjacent pen. Following a 5-h separation period, the kids were weighed and then joined with their dams to nurse. After kids had finished nursing (approximately 15 min), they were reweigh. Milk yield for the 5-h period was taken as the difference in kid weight before and after nursing. To determine milk composition, samples were obtained once weekly by hand milking out the ewes before allowing the lambs to nurse. The samples were collected into plastic vials preserved with Microtabs, stored at 4°C, and analyzed for total solids by drying a weighed 10ml/sample to a constant weight at 105 °C for 24 hours. Fat was determined using Gerber method. Milk protein was determined by Kjeldahl method ($N \times 6.38$). Ash was determined by evaporating 10ml of milk to dryness and ashed in a muffle furnace at 450°C for 6 hours (or 600°C for 2 hours). Lactose was calculated using the following formula:

$$\text{Lactose} = 100 - (\text{ash} + \text{moisture} + \text{fat} + \text{proteins})$$

Hematological parameters

Blood sampling was performed weekly throughout the 8-week experimental period. Blood samples were obtained in the morning before feeding and watering from the external jugular vein and were placed immediately in ice. Heparin was used as an anticoagulant and plasma was obtained by centrifugation and stored at -20 °C until used for analyses. Uncoagulated blood was tested, shortly after collection, for hemoglobin (Hb), total erythrocyte count (TEC), packed cells volume (PCV) and total leukocyte counts (TLC). Blood Hb concentration was determined by the cyanomethemoglobin procedure (Wintrobe, 1965). Erythrocytes and leukocytes were counted on AO Bright line hemocytometer using a light microscope.

Biochemical parameters

Plasma was analyzed for total protein (TP) by the Biuret method according to Henry *et al.* (1974). Albumin (A) concentration was determined according to Doumas *et al.* (1977). Globulin (G) concentration was determined as the difference between total protein and albumin. Plasma glucose concentration was estimated according to Hyvarinen and Nikkila (1962). Urea and creatinine were determined in plasma by the methods of Patton and Crouch (1977) and Henry *et al.* (1974), respectively. Plasma total bilirubin was measured using the method of Walters and Gerade (1970). Plasma was assayed for cholesterol by the method of Watson (1960).

Plasma alanine aminotransferase (ALT) and aspartate aminotransferase (AST) activities were assayed by the method of Reitman and Frankel (1957). Alkaline phosphatase (ALP) activity was measured in plasma (Principato *et al.*, 1985). For assaying acid phosphatase (AcP) activity, the method of Moss (1984) was used. Plasma lactate dehydrogenase (LDH) activity was determined by the method of Cabaud and Wroblewski (1958). Glutathione S-transferase (GST) activity was determined in plasma according to Habig *et al.* (1974), using p-nitrobenzylchloride as a substrate. Thiobarbituric acid- reactive substances (TBARS) were measured in plasma by using method of Tappel and Zalkin (1959).

Statistical analysis

Data were analyzed by a General Linear Model (GLM) procedure using SAS statistical package (SAS, 1986). Variation between means were compared by Duncan's Multiple Range Test (Snedecor and Cochran, 1980). The following model was used:

$$Y_{ijk} = \mu + a_i + b_j + ab_{ij} + e_{ijk}$$

where:

Y_{ijk} = experimental observation,

μ = Overall mean,

a_i = treatment effect

b_j = week effect

ab_{ij} = interaction effect of treatment and week

e_{ijk} = random error

RESULTS

1. Body weight and feed intake

Body weight (BW) and dry matter intake (DMI) of the does were not significantly ($P>0.05$) affected by rbST treatment (Table 2). Kids of rbST-treated does had higher average daily gain (ADG) ($P<0.05$) than the kids of control goats by 11 and 10.5 % for 50 mg and 100 mg rbST, respectively (Table 2).

Table 2. Effect of rbST on body weight and dry matter intake (DMI) of lactating goats and on growth performance of their kids (Means±SE)

Parameter	Group		
	Control	50mg rbST	100 mg rbST
No. of does	5	5	5
Initial weight (kg)	28.60±2.8	29.75±3.1	29.00±3.8
Final weight (kg)	28.25±2.6	29.87±2.3	28.90±2.6
DMI (kg/d)	1.601±24	1.649±22	1.645±25
No. of kids	5	5	5
Initial weight (kg)	7.51±0.43	7.43±0.55	7.46±0.57
Final weight (kg)	13.76±0.76	14.41±0.42	14.37±0.7
ADG (g/d)	104.20±6.26 ^b	115.76±5.28 ^a	115.16±8.51 ^a

^{ab} Within a row, means with different superscript letters differ significantly ($p < 0.05$).

^{*} The improvement (%) in ADG of kids suckling rbST-treated does was calculated as a percent of control group.

2. Milk yield and composition

The treatment of does with rbST increased rapidly milk yield after the onset of treatment (Fig. 1). Average increases in milk yield for does treated with 50 mg or 100 mg of rbST were 24.3 and 22.5 % above the control group, respectively (Table 3). The improvement in milk yield was 35 % in the first 3 weeks in does treated with 50 mg rbST and started to decline from the sixth week of treatment (Fig.1). While, the enhancement in milk yield due to the administration of 100 mg rbST continued until the fifth week of the treatment and then declined. No significant difference was noted between the 50 and 100-mg treatment groups. The improvement in milk yield due to rbST treatment was concomitant with a slight increase in the percentages of total solids, protein and fat, but the percentages of ash did not alter with the treatment. Concentration of lactose significantly increased ($P < 0.05$) in treated does with both 50 mg and 100 mg of rbST as compared with the control (Table 3). The improvement in milk yield and composition was approximately similar in 50 mg or 100 mg of rbST treated animals.

($p < 0.05$).

* The improvement (%) in milk yield of rbST-treated does was calculated as a percent of control group.

3. Hemato-biochemical parameters

The present data showed that hematological parameters (Hb, TEC, PCV, and TLC), plasma proteins (TP, A and G), enzyme activities (AST, ALT, AcP, AIP, and GST) and the levels of thiobarbituric acid-reactive substances did not change in treated does with both rbST administration as compared to the control animals (Tables 4 and 5). Treatment with low or high doses of rbST caused significant ($P < 0.05$) decrease in the levels of plasma urea and total bilirubin in a dose dependent manner. While, the concentrations of creatinine and cholesterol insignificantly ($P > 0.05$) decreased. On the other hand, the levels of glucose significantly ($P < 0.05$) increased in treated groups with both low and high doses of rbST compared to control (Table 4).

Table 4. Effect of rbST on hematological parameters of lactating goats (Means±SE)

Parameter	Group		
	Control	50 mg rbST	100 mg rbST
Hb (g/dl)	14.5±0.21	14.5±0.25	14.3±0.23
PCV %	30.1±0.67	29.7±0.76	29.4±0.49
Erythrocytes ($\times 10^6$)	9.4±0.29	9.6±0.47	9.2±0.41

DISCUSSION

The insignificant increase in body weight (BW) and dry matter intake (DMI) with rbST administration in the present study (Table 2) is in agreement with Disenhaus *et al.* (1995), Davis *et al.* (1999) in goats and Chilliard (1988a) in cows. However, the response to somatotropin can be variable. For example, Tripp *et al.* (1998) reported that ST injection resulted in increased body weight gain and feed efficiency. The present results showed that average daily gain (ADG) of kids that were suckling rbST-treated does was higher than for kids of untreated does during treatment period (Table 2). Also, Davis *et al.* (1999) found that average daily gain of kids that were suckling bST-treated does was higher ($P<0.05$) than for kids of untreated does. From the present data it is clear that the increase in ADG of the kids of rbST-treated does was affected without change in DMI or BW of does. Similar responses in milk yield by lactating goats and cows without corresponding increase in DMI have been reported by Peel and Bauman (1987) and Davis *et al.* (1999). McLaughlin *et al.* (1991) reported that performance responses due to treatment with bST were reflected by changes in circulating glucose, blood urea nitrogen, and insulin-like growth factor I (IGF-I) concentrations. Also, Min *et al.* (1997) and Faulkner (1999) found that bST increased IGF-1 in milk and plasma and could be one of the processes involved in stimulating milk synthesis. Prosser *et al.* (1991) demonstrated that increased milk secretion occur in goats in which milk and mammary IGF-1 concentrations increased.

In general, milk response is very small or negligible when bST is administered in early lactation during the interval immediately postpartum and prior to peak milk yield (Bauman, 1992). For the 8 weeks treatment period at 30-40 days postpartum, both doses of rbST resulted in a significant ($P<0.05$) increases in milk yield (24.3% for does treated with 50 mg and 22.5% for does treated with 100 mg) compared with milk yield of does on the control group. The pattern of milk yield response to sustained-release rbST in the present study (Fig. 1) was similar to that reported due to daily injection in goats (Disenhaus *et al.*, 1995) and in cows (Chilliard, 1988b). The average response of goats injected daily with rbST at 5 mg/d/animal was 28.6% increase in milk production for short-term experiment (28 days, Disenhaus *et al.*, 1995). Also, Disenhaus *et al.* (1992) found that, for lactating goats injected daily with rbST for 4 wk, milk yield increased significantly and exceeded the yield of untreated

goats by nearly 26%. This finding is similar to the present results of both doses of rbST (Table 3). Somatotropin is a homeorhetic controller that shifts the partitioning of nutrients so that more are used for milk synthesis (Peel and Bauman, 1987). Thus, effects are primarily, perhaps exclusively, on directing the use of absorbed nutrients. This involves coordinating the metabolism of various body organs and tissues. These orchestrated changes in tissue metabolism involve both direct effects on some tissues (e.g., adipose, liver) and indirect effects mediated by somatotropin-dependent somatomedins (e.g., IGF-1) for other tissues (e.g., mammary) (Bauman, 1992). The mechanism of bST to exert its galactopietic effect is complex and involves a multiplicity of events in whole animal. The results obtained by Faulkner (1999) indicated that there were increases in the availability of glucose within the mammary epithelial cell in response to growth hormone treatment that would result in increases in the rate of lactose synthesis and hence stimulation of milk production. Also, they found increases in the concentrations of IGF-1 in milk and plasma and could be one of the processes involved in stimulating milk synthesis. In addition, somatotropin appears to promote milk production by a partitioning effect on absorbed nutrients, so to supply more substances for mammary synthesis, and also the level of nutrition may influence yield responses for milk and milk composition, and nutrient flow in bST-treated lactating ruminants (Bauman and Currie, 1980). Also, the increase in milk synthesis with STH treatment most likely involves changes in the activity of key regulatory enzymes resulting in an increased synthesis rate per epithelial cell. However, the possibility of an increase in mammary cell numbers cannot be excluded. In either case, somatotropin affects the maintenance of lactation as evidenced by the changes observed in the shape of the lactation curve (Bauman and Eppard, 1987). This role would presumably involve an altered turnover of epithelial cells and cellular components so that the normal loss of cells or the normal decline in biochemical activity per cell was reduced with STH treatment (Bauman and Eppard, 1985).

Gross composition of milk (fat, protein, and lactose content) is not substantially altered due to bST administration (Peel and Bauman, 1987). Linn (1988) reported that milk components have been examined in most bST production trials. There can be minor changes, primarily in fat content of milk, during the first few weeks of bST supplementation as the cow's metabolism and voluntary feed intake adjust. However, these changes are temporary and minor when compared with variations normally occurring over a lactation cycle. Although, the lactose content of milk is relatively constant, the content of fat and protein normally varies widely because of many factors, including genetic, breed, stage of lactation, age, diet composition, nutritional status, environment and season. The present results showed that there is no significant difference between control and treated groups with low or high doses of rbST in the average values of milk protein, total solids, fat and ash, while lactose levels increased (Table 3). Also, there is no change in milk composition in response to bST was observed in goats (Davis *et al.*, 1999). The ability of bST to spare amino acids from catabolism and consequently to decrease urinary excretion of nitrogen was demonstrated (Disenhaus *et al.*, 1995). The increase in lactose level (Table 3) is in agreement with the finding of Molento *et al.* (2002) found that milk yield, lactose percent, lactose yield and IGF-I levels were increased during rbST administration. In addition, Min *et al.* (1997) reported that treatment with bovine growth hormone increased yields of milk, fat, lactose and weight of the mammary gland.

Urea concentration in plasma may be diminished by bST treatment. The decrease in plasma urea (30 and 40% for low or high doses, respectively) of does treated with rbST (Table 4) is in agreement with the results of goats treated with bST (Disenhaus *et al.*, 1995). Also, Davis *et al.* (1999) reported that changes in plasma concentration of glucose, total protein, or urea of lactating goats were observed in response to bST treatment. McLaughlin *et al.* (1991) found that blood urea nitrogen was decreased in bST-treated lamb. Min *et al.* (1997) reported that treatment with bovine growth hormone increased circulating concentrations of growth hormone, insulin-like growth factor-I, and nonesterified fatty acids and decreased urea concentrations in ewes. In addition, Eisemann *et al.* (1989) found that plasma concentration urea-N and alpha-amino-N decreased with bST in beef steers. Since the plasma levels of urea is the index of hepatic amino acids oxidation and of ruminal ammonia fermentation, therefore its decrease may reflect a higher amino acids removed from blood for milk protein biosynthesis.

Glucose homeostasis provides a clear example of the coordinated responses that occur with bST treatment of lactating cows (Bauman, 1992). With bST uses, glucose production by the liver increases, and its oxidation by body tissues decreases. Overall, these changes quantitatively are sufficient to account for the extra glucose required for milk synthesis by bST-treated cows (Bauman, 1992). The present results showed that plasma glucose increased by 43% and 51 % for low or high doses of rbST. Eisemann *et al.* (1989) found that plasma concentration of somatotropin, insulin and glucose increased, while urea-N and alpha-amino-N decreased with bST in beef steers. Supplementation with bST may increase input of glucose into blood circulation by promoting gluconeogenesis from digestive precursors and from peripheral precursors, such as amino acids and glycerol (Knapp *et al.*, 1992). Also, Molento *et al.* (2002) found that recombinant bovine somatotropin (40 mg/day for 6 days) caused a peripheral resistance to insulin or increased liver gluconeogenesis or both. The reduction in the ability of insulin to inhibit hepatic glucose synthesis and to stimulate glucose use by peripheral tissues represents a series of coordinated responses whereby more glucose can be used for milk synthesis while preserving the ability of the animal to maintain glucose homeostasis (Bauman, 1992). In addition, the effects on glucose and insulin has been reported in lactating cows and described usually as diabetogenic activity of bST (Chillard, 1988 a&b). The importance of these effects in the shift of the partitioning of nutrients is also because the mammary gland processes can enhance lactose synthesis and the osmotic regulator of milk volume (Gallo and Block, 1990).

Table 4 showed that hematological parameters (Hb, PCV, TEC and TLC), plasma proteins (total protein, albumin and globulin), creatinine and cholesterol did not change in does treated with rbST as compared with control. Also, the activities of plasma AST, ALT, AcP, AIP and GST, and the concentrations of TBARS were not affected by rbST treatment as compared to the control group (Table 5). On the other hand, treatment with rbST caused reduction in total bilirubin concentration. Also, Eppard and Bauman (1987) reported that treatment with bST did not cause any significant change in PCV, HB, RBC, WBC, total protein, albumin, globulin, creatinine, AST, while blood urea nitrogen decreased in dairy cows. The activities of plasma AST and ALT, which are commonly used as indicators of liver cell damage and death, was not affected by the treatment with rbST (Gallo and Block, 1990). In addition, Davis *et al.* (1999) reported that treatment with bST did not affect plasma

concentrations of total protein of lactating Angora does. Early *et al.* (1990) found that serum electrolytes, protein and most enzyme activities were similar in control and bST steers. Serum urea, creatinine and cholesterol concentrations, however, were lower in BST steers, suggesting that nitrogen retention was increased and lipid turnover was decreased by BST. Total and conjugated bilirubin concentrations and glutamate-pyruvate transaminase activity were lower in BST steers. Bauman and Eppard (1985) reported that milk yield responses to STH are perfectly coordinated with the alteration in the metabolism of body tissues as evidenced by the fact that steady state concentrations of blood metabolites are maintained (Tables 4 and 5). The increases in milk yield with rbST treatment (Table 3 and Fig. 1) could not persist through the treatment period unless coordinated changes occurred in body metabolism so that steady-state conditions were maintained. Eppard and Bauman (1987) reported that treatment with bST, physiological processes associated with carbohydrate, protein, lipid, and mineral metabolism all are coordinated to meet the increased mammary requirement for nutrients.

CONCLUSION

Administration of recombinant bST to lactating does once every other week for 60 days at 30-40 days postpartum increased milk yields (25% and 23% for 50 mg or 100 mg, respectively) and kid growth. The levels of milk lactose and plasma glucose increased, but plasma urea decreased. While, there is no significant changes were found in body weight, dry matter intake, hemato-biochemical parameters and milk composition of treated does. Also, there is no significant difference was found between low (50 mg) and high (100 mg) doses of rbST. Based on these results, rbST is efficacious in increasing milk yield up to 24.3% and kid growth up to 50 mg/14 days at 30-40 days postpartum without adverse effects on lactating does.

تأثير المعاملة بهرمون النمو المخلق علي إنتاج ومكونات اللبن وبعض المقاييس الهيماتولوجية و الكيموحيوية في الماعز الحلابية

صبحي محمد سلام، محمد عماد ناصر، مختار إبراهيم يوسف

الدراسات السابقة أثبتت أن هرمون النمو المخلق له القدرة علي زيادة معدل الاستفادة من الغذاء. وحقق هذا الهرمون في الأبقار الحلابية أدي إلي تحسن الكفاءة الإنتاجية لها. بالرغم من أن المعاملة بهرمون النمو المخلق للأغنام والماعز أدي إلي زيادة محصول اللبن لكن الدراسات التي أجريت علي هذه الحيوانات كانت قليلة وأيضاً لمدة قصيرة (أقل من ١٤ يوم) وكانت المعاملة يومياً وليس أسبوعياً أو كل أسبوعين.

لذلك تم إجراء هذا البحث لدراسة تأثير جرعتين مختلفتين (٥٠ و ١٠٠ مجم/حيوان) من هرمون النمو المخلق صناعياً مرة كل أسبوعين علي محصول اللبن وتركيبه وكفاءة نمو ولادات الماعز Kids وبعض المقاييس الهيماتولوجية و الكيموحيوية للماعز الحلابية وكانت المعاملة لمدة ٨ أسابيع.

في هذه الدراسة تم استخدام خمسة عشر من الماعز الدمشقي الحلابية (متوسط وزن ٢٩,١٢ كجم) بعد الولادة من ٣٠ - ٤٠ يوم. والماعز كانت في الموسم الثالث أو الرابع من الحليب. تم تقسيم الحيوانات إلي ثلاث مجاميع متساوية حسب مرحلة الحليب وكمية اللبن. المجموعة الأولى استخدمت كمجموعة ضابطة ، بينما المجموعة الثانية والثالثة تم حقنها تحت الجلد بجرعة ٥٠ و ١٠٠ مجم من هرمون النمو المخلق/حيوان مرة كل أسبوعين لمدة ٦٠ يوم علي التوالي.

أوضحت النتائج أن معدل تناول المادة الجافة ووزن الجسم للأمهات لم يتأثر معنوياً بالمعاملة بهرمون النمو المخلق مقارنة بالمجموعة الضابطة. بينما الزيادة في الوزن اليومي (ADG) للنتاج للأمهات المعاملة بالهرمون كان أعلى عن نتاج المجموعة الضابطة بنسبة ١١% و ١٠,٥% للجرعات ٥٠ ، ١٠٠ مجم علي التوالي. أيضاً المعاملة بهرمون النمو أدت إلي حدوث زيادة سريعة في محصول اللبن. وكان متوسط الزيادة علي مدار التجربة ٢٤,٣% و ٢٢,٥% للجرعات ٥٠ ، ١٠٠ مجم علي التوالي مقارنة بالمجموعة الضابطة. الزيادة في محصول اللبن كانت متسقة مع الزيادة في نسبة المواد الصلبة والبروتين والدهن. بينما لم يحدث تأثير للرماد. وحدث زيادة في تركيز اللاكتوز في كلا المعاملتين مقارنة بالمجموعة الضابطة. وأوضحت النتائج أن الزيادة في محصول اللبن ومكوناته كانت متشابهة في الحيوانات التي عولمت بجرعة ٥٠ مجم أو ١٠٠ مجم. أوضحت النتائج أن المقاييس الهيماتولوجية والبروتين الكلى والأنشطة الإنزيمية ومستوي الأضول الحرة في بلازما الدم لم تتغير معنوياً في الحيوانات المعاملة مقارنة بالمجموعة الضابطة. بينما المعاملة أدت إلي حدوث انخفاض معنوي في مسوي اليوريا والبيليروبين. بينما كان الانخفاض غير معنوي في الكرياتينين والكوليسترول. من ناحية أخرى حدث زيادة معنوية في مسوي الجلوكوز في الحيوانات المعاملة مقارنة بالمجموعة الضابطة.

توصي هذه الدراسة أن المعاملة بهرمون النمو المخلق له القدرة والكفاءة علي زيادة محصول اللبن حتى ٢٤ % ووزن النتائج باستخدام جرعة ٥٠ مجم/حيوان مرة كل ١٤ يوم عند اليوم ٣٠ - ٤٠ بعد الولادة للماعز الحلابة دون ظهور تأثير سلبي علي صحة الأمهات.
