List of abbreviations

Abb.

5-FC	5-fluorocytosin
API 20C	Appareils et proce'de's d'identification
BAL	Bronchial alveolar lavage
C	Candida
CFU	Colony forming units
CSF	Cerebrospinal fluid
DBB	Diazonium blue B salt
DNA	Deoxyribonucleic acid
HIV	Human immunodeficiency virus
ITS	Internal transcribed spacer region
KOH	Potassium hydroxide solution
LPCB	Lactophenol cotton blue
MIC	Minimum inhibitory concentration
MSP-PCR	Mini-micro satellite primed PCR technique
NaCl	Sodium chloride
PCR	Polymerase chain reaction
PFGE	Pulsed field gel electrophoresis
Prolysis-GC-MS	Analytical prolysis-gas chromatography-Mass spectrometry
R	Rhodotorula
RAPD	Random amplification of polymorphic DNA analysis
rDNA	Recombinant- Deoxyribonucleic acid
rpm	Revolution per minute
rRNA	ribosomal Ribonucleic acid
S	Saccharomyces
SBS	Sick building syndrome
SDA	Sabouraud's dextrose agar medium
SDS-PAGE	Sodium dedecyl sulfate polyacrylamide acyl gel electrophoresis
spp	Species
T	Torulopsis

7. SUMMARY

This study was conducted on 1830 samples which were collected from human (100 samples of infected nails of Onychomycosis), diseased animals (350 buffaloes and 290 cows) and apparently healthy animals (400 buffaloes and 285 cows).

The samples collected from diseased cases included mastitic milk samples (150 buffaloes and 100 cows), rectal swabs from animals suffering from diarrhea (100 buffaloes and 90 cows), nasal swabs from animals showing nasal discharge (50 buffaloes and 50 cows) and vaginal swabs from animals suffering from any reproductive disorders (50 buffaloes and 50 cows).

The normal samples were collected from apparently healthy animals including 100 samples from each type of normal milk, rectal, nasal and vaginal swabs of apparently healthy buffaloes, also 60 samples of normal milk from cows and 75 samples from rectal, nasal and vaginal swabs of apparently healthy cows.

Environmental samples included 225 samples which were collected from environment of animal farms (90 air samples, 60 water samples and 75 soil samples) and 180 samples from different places surrounding human (60 samples from each type, air, water and soil).

All the samples were cultured on SDA with chloramphenicol and incubated at 30°C for 48-72 hours for mycological examination. The obtained results revealed that *Rhodotorula* species were isolated from human samples with an incidence of (5%) and from diseased cases of buffaloes with an incidence of (6.7%, 20%, 10% and 16%) from milk samples, rectal, nasal and vaginal swabs, respectively, while those obtained from apparently health buffaloes were with an incidence of (3%, 10%, 10% and 10%) from milk samples, rectal, nasal and vaginal swabs.

Rhodotorula isolates presented (8%, 22.2%, 24% and 22%) from diseased cases of cows and (10%, 20%, 13.3% and 9.3%) from apparently healthy cases of cows from milk samples, rectal, nasal and vaginal swabs, respectively.

Rhodotorula species were isolated with an incidence of (13.3%, 20% and 20%) from environment surrounding animals and with an incidence of (13.3%, 20% and 13.3%) from environment surrounding human from air, water and soil, respectively.

Yeast colonies which have carotenoid pigment were subjected for further identification by phenotypic and genotypic methods. All isolates which were identified morphologically by macro and microscopically examination revealed carotenoid

pigments colonies on SDA with orange to red surface color, large round, ovoid or elongated cells with lactophenol cotton blue, large gram positive yeast cells with Gram's stain and absence of hyphae and pseudohyphae with large blastospore on rice agar.

The identification of *Rhodotorula* isolates into species was performed using API 20C Aux system according to its substrate assimilation profile. Among 25 selective isolates, 22 isolates were *R. mucilaginosa*, 2 were *R. glutinis* and one was *R. minuta*.

On the other hand, 14 isolates were examined by molecular method polymerase chain reaction (PCR). ITS 2 of PCR products obtained from all isolates identified them as genus *Rhodotorula* at 429 bp.

DNA sequences for 5 isolates from them identified 3 as *R. mucilaginosa*, one as *R. slooffiae* and one was identical to *Rhodotorula* species known in gene bank as strain CBS 8885.

On the other hand, antifungal sensitivity test for *Rhodotorula* isolates revealed high sensitivity for nystatine, followed by ketoconazole and clotrimazole, while resistance was observed with fluconazole and amphotericin B.
