ABSTRACT

Two experiments were carried out at the experimental farm of Kafr El-Hamam Agriculture Station, Egypt during the two successive seasons 2017/2018 and 2018/2019, for five crosses; (Sids12 x Line44), (Sids12 x Line35), (Line44 x Line20), (Line44 x Shandweel 1) and (Line20 x Sakha93) to study nature of gene action, heterosis, heritability and expected genetic advance for the first experiment and actual response, heritability, expected genetic gain and develop new wheat pure lines of high grain yield/ plant for second experiment under normal and water stress conditions. The results indicated that water deficit reduced means of all six generations compared with normal irrigation for all traits except proline content. The 4th cross showed positive significant relative heterosis and heterobeltosis under both conditions for days to heading, days to maturity and grain yield per plant. The six-parameter model (complex) was fitted for explaining genetic variation for days to maturity and grain yield/ plant in all crosses under irrigation and water stress conditions. Moderate to high estimates of narrow sense heritability (h^2) were found for days to maturity, spike length, spike density, number of spikelets/spike, for number of grains /spike and 1000-grain weight/plant. Low to moderate estimates of narrow sense heritability (h^2) were found for number of spikes/plant, for grain yield/plant. Whereas, the second experiment, all studied traits of F_2 and F_3 families had significant differences in the five crosses under both conditions. The estimates of phenotypic coefficients of variability (PCV) were little higher than those of genotypic coefficients of variability (GCV) for all traits in five crosses

under both conditions, indicating the low effect of the environment on the studied characters. The ranges, means, genetic variances, PCV, and GCV estimates for most studied traits were higher under normal irrigation than corresponding estimates under water stress condition in five crosses for F₂ and F₃ populations. Estimation of heritability (h^2_{Bs}) and genetic advance (GA) were higher under normal irrigation than estimation under water stress condition for most studied traits in the F₂ and F₃ generations for the five wheat crosses. Positive values of correlation (r) between offsprings (F₃) and parents (F₂) in yield and its components under normal irrigation and water stress conditions were estimated.

ACKNOWLEDGMENT

First and foremost, I feel always indebted to ALLAH the most beneficent and merciful.

My sincere thanks to Prof. Dr. M. M. A. Ali, Professor of Plant Breeding Agronomy Department, Faculty of Agriculture, Zagazig University for his supervision, drawing the plan of the work, valuable advice and continuous help and encouragement during this study.

Also, I would like to express my indebtedness to Dr. Manal A. Hassan, Senior Researcher, head of Kafer El Hamam, Research Station, Zagazig ARC, for her supervision, valuable help and kind encouragement.

Many thanks are also due to all staff members of Agronomy Dept., Faculty of Agric., Zagazig University for their help and kind encouragement.

The author feels deeply thanks for all staff members of Kafer El Hamam Research Station at Zagazig for their encouragement and friendly help.

Special thanks are also due to my father (Dr. Abdallah Swelam) and my family for their ameliorate and encouragement through this research work.
